

Short Summary: Key Findings — Real Estate Sales Analysis (2011–2022) *

1. *Market growth followed by a sharp correction. *

Sales rose steadily from \$2.6B (2010) to \$25.35B (2020), spiked to a peak of \$40.25B in 2021, then fell nearly 45% to \$22.11B in 2022. The 2021 figure is an anomaly, not the market's new normal.

2. *Town-level pricing is largely stable, with two outliers. *

Most towns hold sales ratios between 0.70–1.30 (properties selling close to assessed value) — a sign of healthy, well-calibrated assessments. Bellingham (37.15) and Keene (21.30) break this pattern sharply, most likely due to isolated Single-Family transactions or data errors rather than real market shifts.

3. *Value is concentrated in one property category. *

Although the market includes 11 property types with fairly even representation by count, Single Family homes alone account for \$143.85B in sales — more than 2.6x every other category combined. Diversity in category count doesn't mean diversity in revenue contribution.

4. *Sales activity is seasonal. *

Monthly/yearly trend charts show recurring peaks and troughs across the year, useful for planning municipal review cycles and staffing around high-transaction periods.

5. *A small number of towns drive most transaction value. *

The "Total Sale Amount by Town" analysis shows sales concentrated among top-performing towns, while the majority contribute comparatively little — relevant for prioritizing zoning attention and tax-policy focus.

*Recommendation: *

Anchor forecasting and resource planning to the \$22–25B sustainable range rather than the 2021 peak. Prioritize Single Family and Condo categories in demand/pricing models. Validate the Bellingham and Keene records before using them in town comparisons, since their sales ratios likely reflect data anomalies rather than true market behavior.
